Programming Homework 1

Due Time: 11:59 PM, September 17, 2020

Objective:

To understand and experiment with process creation and pipes in Linux.

Problem Statement:

D.R. Kaprekar's Operation, a process named after Indian mathematician D.R. Kaprekar, is described as follows.

Given any three- or four-digit number where not all digits are the same, i.e., not 111, 8888, etc.,

1. Rearrange the digits of the number in descending and ascending orders in order to make the largest and smallest numbers out of those digits. For example, given 2418, the largest number using these four digits is 8421 and the smallest one is 1248.
2. Subtract the smaller number from larger one.
3. Take the result from step 2. Go to step 1 and repeat the process until the result converges.

Given the number 5438, the Kaprekar's process is:

$8543 - 3458 = 5085$
 $8550 - 558 = 7992$
 $9972 - 2799 = 7173$
 $7731 - 1377 = 6354$
 $6543 - 3456 = 3087$
 $8730 - 378 = 8352$
 $8532 - 2358 = 6174$
 $7641 - 1467 = 6174$
 $7641 - 1467 = 6174$
..... (converged)

For any 3-digit number where not all digits are the same, the final result will be **495**!

Requirement:

Write a C program using the `fork()` system call to create a child process that executes Kaprekar's Operation for a 3-digit number. The child process is required to **print out** the intermediate results as shown in the example above. The input number should be provided from the command line. For consistency, use the number "123" as the testing input.

In addition, the child process should inform the parent process about the completion of the operation, i.e., when the operation converges to a fixed number. This is done by sending the final converged number to the parent process using an ordinary pipe (refer to figure 3.25-3.26 for pipe creation). Upon receiving the message from the child, the parent process is required to **print out** the message. Have the parent invoke the `wait()` call to wait for the child process to complete before exiting the program.

Steps:

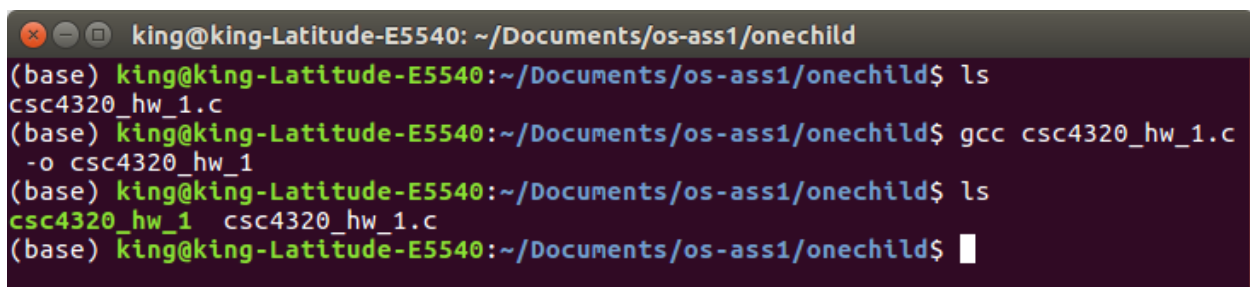

- Download the incomplete source file `hw1.c` from iCollege. The incomplete code obtains the input number and assigns it to variable `n`.
- Complete the code
- Compile the C source file using `gcc` (see screenshot 1 below)
- Take a screenshot of the program intermediate results and final output (see screenshot 2 below as a sample output).

Submission:

Submit the following to iCollege:

- The C source file `hw1.c`
- A report in PDF that includes (1) the screenshot of your program output and (2) a copy of your C source code from `hw1.c` file

Failure to follow the submission requirement will cause 10% deduction in the score.

```
